     The emergence of clinical isolates of methicillin-resistant Staphylococcus
AB
     aureus with reduced susceptibility to vancomycin has prompted a search for
     new and novel therapeutic agents active against S. aureus.
     Lysostaphin, a peptidase produced by Staphylococcus simulans,
     specifically cleaves the glycine-glycine bonds unique to the interpeptide
     cross-bridge of the S. aureus cell wall. The effectiveness of various
     regimens of dosing with intravenous lysostaphin was
     compared to that of vancomycin in the rabbit model of aortic valve
     endocarditis caused by a clinical methicillin-resistant S. aureus isolate.
     All animals were treated for a total of 3 days. The most active regimen,
     lysostaphin given three times daily, produced sterile vegetations
     in 10 of 11 treated rabbits, with a mean reduction in vegetation bacterial
     counts of 8.5 log10 CFU/g compared to the counts in the untreated
     controls. In contrast, vancomycin given twice daily sterilized no
     vegetations and reduced vegetation bacterial counts by only 4.8 log10
     CFU/g. Lysostaphin given once daily was less effective, reducing
     mean vegetation bacterial counts by only 3.6 log10 CFU/g, but the
     combination of lysostaphin once daily and vancomycin twice daily
     reduced the mean vegetation bacterial density by 7.5 log10 CFU/g, a result
     that was significantly better than that for either regimen alone (P <
     0.05). Lysostaphin was well tolerated by the rabbits, with no
     evidence of immunological reactions following up to 9 weeks of
     intravenous administration. We conclude that lysostaphin
     given alone or in combination with vancomycin is more effective in the
```

treatment of experimental methicillin-resistant S. aureus aortic valve

endocarditis than vancomycin alone.
